

Operational Analysis & Strategy Proposal

The analysis of inter-terminal container transfers between PCT and SCY identifies the **SCY Yard processing stage** as the primary bottleneck in the shuttle cycle. This stage consistently contributes the highest proportion of total cycle time, indicating inefficiencies in unloading and loading operations within SCY. While travel times between terminals remain relatively stable across all three vendors, delays increase significantly once containers arrive at SCY, suggesting that operational constraints—not transportation—are the main issue.

Further temporal analysis shows that **evening shifts experience longer delays**, likely due to higher traffic volume, resource limitations, and yard congestion. Vendor comparison indicates minimal differences in travel efficiency, reinforcing that the bottleneck is internal to yard operations rather than vendor performance.

Recommendations

1. Optimize SCY Yard Operations

Increase the availability of handling equipment (e.g., cranes, forklifts) and workforce during peak hours, particularly in the evening shift. Implementing a structured scheduling system or priority-based container handling can reduce idle time and improve turnaround efficiency.

2. Implement Real-Time Monitoring System

Introduce a real-time tracking dashboard to monitor container movement and yard congestion. This will enable proactive decision-making, such as redistributing workload, minimizing truck queues, and improving coordination between PCT and SCY.

By addressing inefficiencies within SCY Yard and improving operational visibility, RSGT can significantly reduce total cycle time and enhance overall logistics performance.
